Credit Card Fraud Detection using Machine Learning Model.

<u>Problem Statement</u> - For many banks, retaining high profitable customers is the number one business goal. Banking fraud, however, poses a significant threat to this goal for different banks. In terms of substantial financial losses, trust and credibility, this is a concerning issue to both banks and customers alike.

In the banking industry, credit card fraud detection using machine learning is not only a trend but a necessity for them to put proactive monitoring and fraud prevention mechanisms in place. Machine learning is helping these institutions to reduce time-consuming manual reviews, costly chargebacks and fees as well as denials of legitimate transactions.

The problem statement chosen for this project is to predict fraudulent credit card transactions with the help of machine learning models.

In this project, we will analyze customer-level data that has been collected and analyzed during a research collaboration of Worldline and the Machine Learning Group.

Steps to be taken in the Project is sub-divided into the following sections. These are:

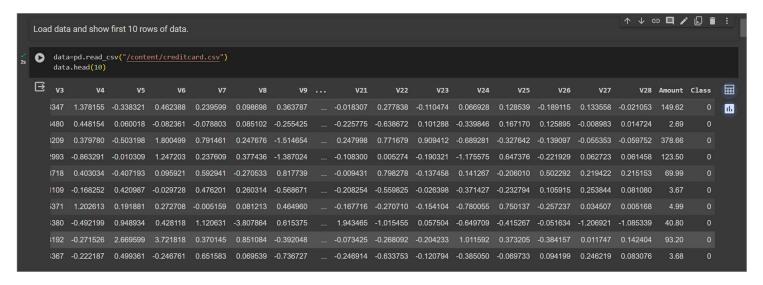

- Load the necessary libraries such as Numpy, Pandas, sklearn.model etc.
- Loading the dataset as csv file and showing first ten rows.
- Drop the unnecessary columns from the data.
- Calculate statistical values and round them up to 3 decimal places.
- Checking for null values and return their sum of numbers of true values in each column.
- Handle the null by mean of all values fill into them.
- Extracting all information about data.
- Checking shape of data.
- Visualization on different species of <u>credit cards transaction information</u> using python data visualization.
- Data preprocessing or (Data cleaning) performed by the one hot encoding in this process we change categorical data into numerical data and the technique is called feature Engineering.
- Splitting the cleaned data into dependent and independent variables.
- Splitting the data into train and test sets with train_test_split using sklearn library.

Shahjan Khan

- Import different kind of Classification Models and Train that model with the help of .fit().
- Predicting the trained models and then checking their accuracy score and confusion metrics of the model using confusion metrics & accuracy score.
- Then recall the train_test_split and split the data into training and testing set with different models.
- Then predicting the trained models and checking the accuracy of model and check the accuracy difference.
- And finally predict whether the classification (or detection) of Credit cards is generated or not.
- > Step-1 Import necessary libraries.

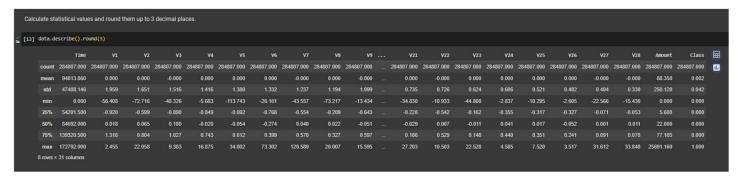

> <u>Step-2</u> – Loading the dataset as csv file and showing first ten rows.

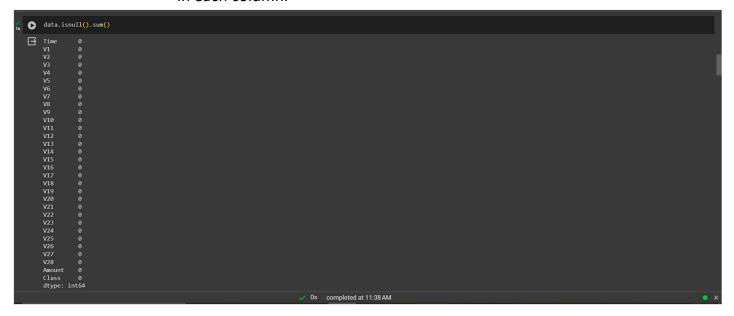

Shahjan Khan

> Step-3 – Calculate statistical values and round them up to 3 decimal places.

> <u>Step-4</u> — Checking for null values and return their sum of numbers of true values in each column.

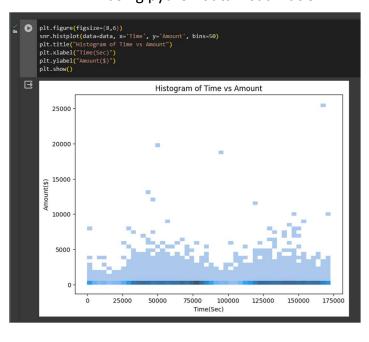

> <u>Step-5</u> – Extracting all information about data.

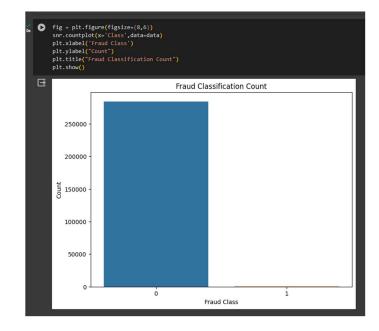

> Step-6 - Checking shape of data.

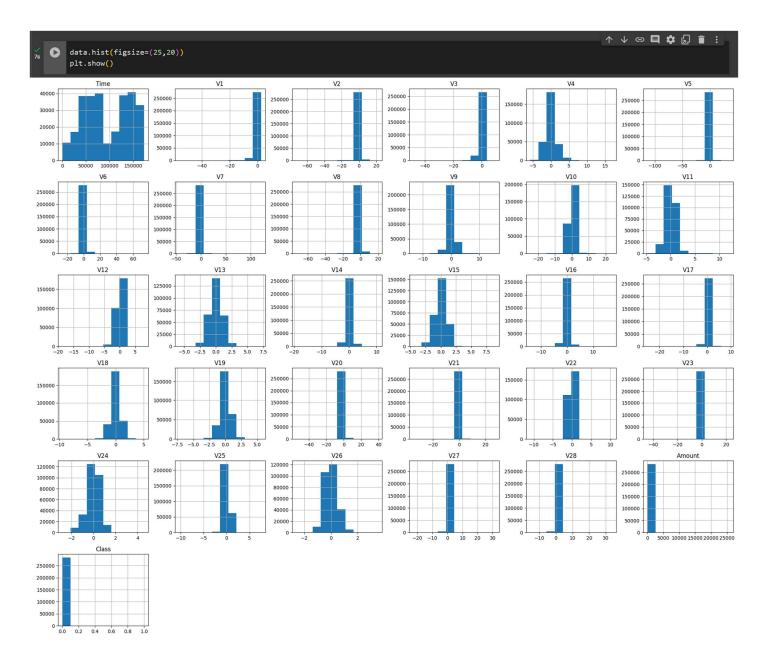

Step-7 – Visualization on different species of <u>credit cards transaction information</u> using python data visualization.

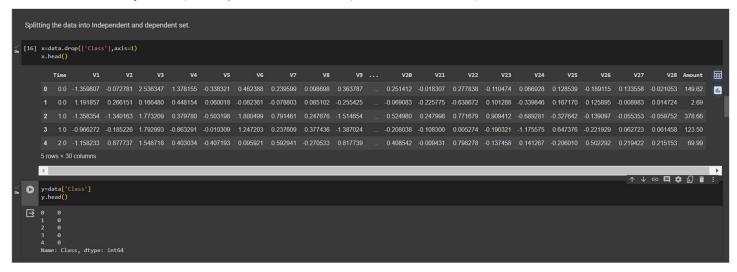

Shahjan Khan

> Step-8 – Splitting the data into dependent and independent variables.

> Step-9 – Splitting the data into training and testing sets.

<u>Step-10</u> – Import first machine learning model K-Nearest neighbor taking n neighbor=5.

> Step-11 – Train the model using .fit() function.

> Step-12 - Making predictions on model.

```
Make predictions on model.

[ ] predictions=neighbor.predict(x_test)
    print(predictions)

[0 0 0 ... 0 0 0]
```

> Step-13 – Checking confusion metrics and accuracy score of model.

```
Check confusion metrics and check accuracy score.

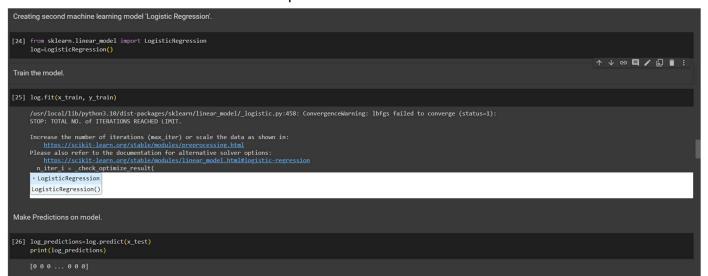

[22] from sklearn.metrics import confusion_matrix, accuracy_score cm=confusion_matrix(y_test, predictions) ac=accuracy_score(y_test, predictions) print(cm)

[[56869 1] [ 85 7]]

[23] print(ac)

0.9984902215512096
```

> <u>Step-14</u> – Import the Second Machine Learning Model 'Logistic Regression' and train model and then make prediction.

<u>Step-15</u> – Print a confusion metrics and check accuracy score for Logistic Regression Model.

```
Check confusion metrics and accuracy score.

from sklearn.metrics import confusion_matrix, accuracy_score cm=confusion_matrix(y_test, log_predictions) ac=accuracy_score(y_test, log_predictions) print(cm)

[56851 19]
[37 55]]

[28] print(ac)

0.9990168884519505
```

> <u>Step-16</u> – Import the Third Machine Learning Model Decision Tree and train model and then make prediction.

<u>Step-17</u> – Print a confusion metrics and check accuracy score for Support Vector Machine Model.

```
Check confusion metrics and accuracy score.

| Section |
```

<u>Conclusion</u> – Here, we have to focus on a high recall in order to detect actual fraudulent transactions in order to save the banks from high-value fraudulent transactions,

After performing several models, we have seen that on performing Machine Learning models I got 99% of accuracy of model by using K-Nearest Neighbor algorithm of Machine Learning, I got 99% of accuracy of model by using Logistic Regression algorithm of Machine Learning and I got 99% of accuracy of model by using Decision Tree algorithm of machine Learning. Overall I got 99% of accuracy for the complete Machine Learning Model of Credit Card Fraud Detection.
